How to Make Sure Your ASP.NET Core Keep Running on IIS

📅 September 16, 2022 👤 Javier Huthon

In this post, I will advise how to make your ASP.NET Core always running on IIS. This ASP.NET Core web application which hosts a background task via the [IHosedService](#) interface.

If you have an ASP.NET or an ASP.NET core which hosts a background job that needs ↑
always run, want to preload the application for performance instead of waiting for the initial

request to hit the app, or just get some tips on IIS, then read on.

Application does not auto start and goes into idle

The ASP.NET core module handles requests for an ASP.NET core application and manages the process under which the application runs. Per the documentation, the module does not start the process for the ASP.NET core app until it receives an initial HTTP request.

The module starts the process for the ASP.NET Core app when the first request arrives and restarts the app if it crashes. This is essentially the same behavior as seen with ASP.NET 4.x apps that run in-process in IIS that are managed by the [Windows Process Activation Service \(WAS\)](#).

As the behavior of an ASP.NET core module is similar to the WAS, the module also terminates the application it has not received a HTTP request for the application after a predefined period of time (Idle time-out). This lazy loading feature is by design to efficiently manage resources.

Keeping the app to run continuously on IIS

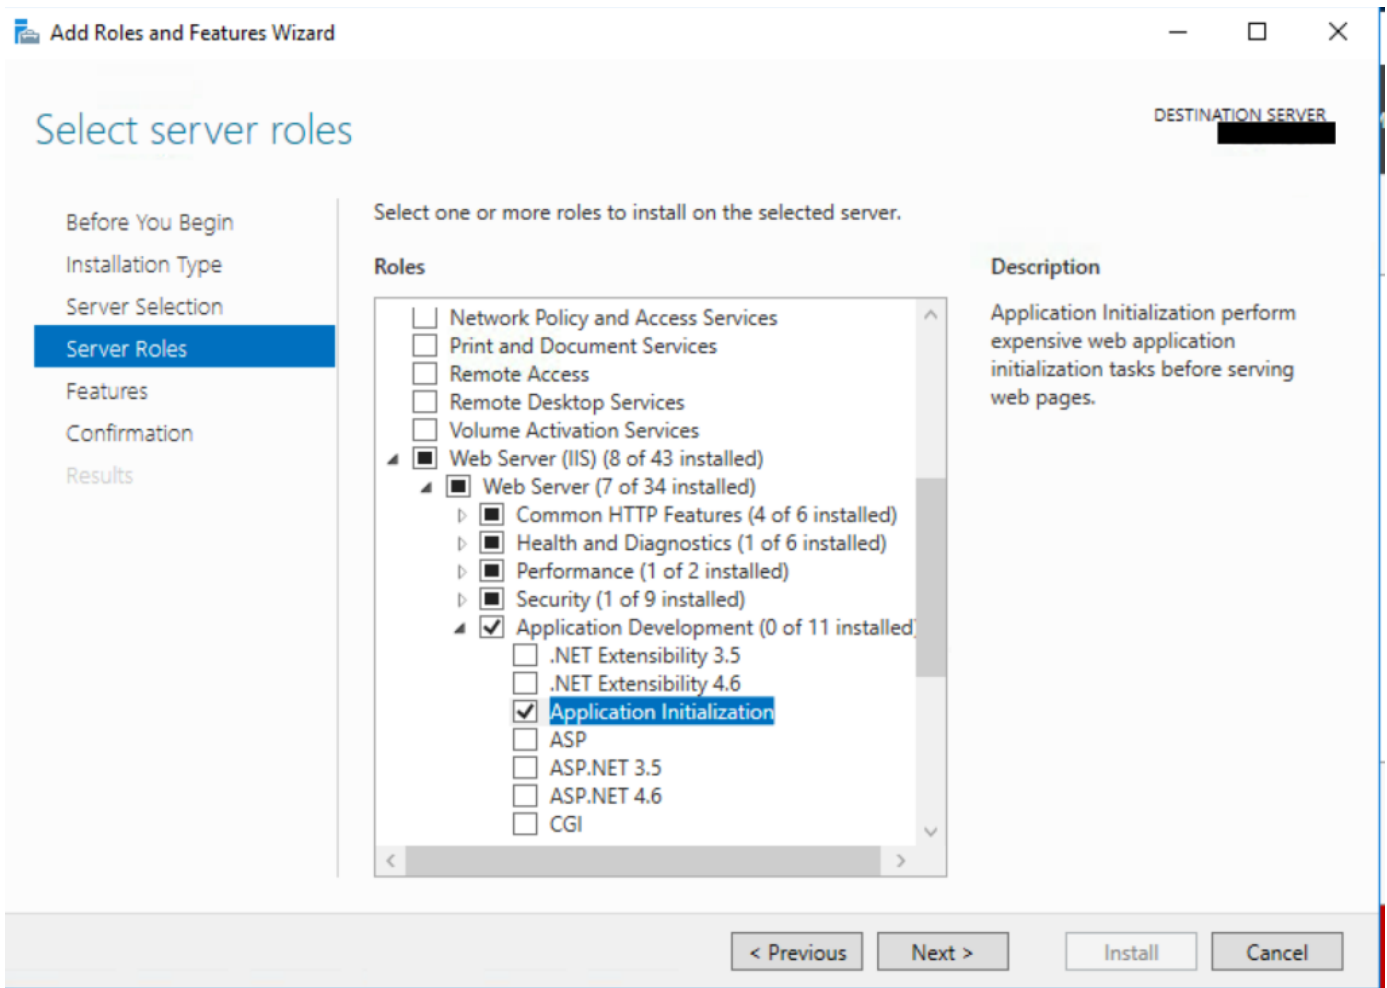

Do the following to keep an ASP.NET core application auto start and always run on IIS:

1. Install the Application Initialization Module

The application initialization module allows IIS to preemptively perform initialization tasks such as making the initial HTTP request to your application, or call your custom logic to perform whatever you desire to warm up your app.

I find it necessary to install the module even though the settings for making an application auto start and always running are there on IIS 10 which is the server I am using.

2. Configure the app pool

In IIS Manager, right click on the application pool under which the application runs and select “Advanced Settings”. Update the following values:

- Set the .NET CLR version to v4.0.
- Set start mode to “Always Running”.
- Set Idle Time-Out (minutes) to 0.

↑

Managed Pipeline Mode	Integrated
Name	
Queue Length	1000
Start Mode	AlwaysRunning
▼ CPU	
Limit (percent)	0
Limit Action	NoAction
Limit Interval (minutes)	5
Processor Affinity Enabled	False
Processor Affinity Mask	4294967295
Processor Affinity Mask (64-bit c	4294967295
▼ Process Model	
> Generate Process Model Event L	
Identity	ApplicationPoolIdentity
Idle Time-out (minutes)	0
Idle Time-out Action	Terminate

Name

[name] The application pool name is the unique identifier for the application pool.

The Idle time-out value of 0 means your application never time out. IIS does not kill your application even if it has not received any HTTP request for an indefinite time.

Setting the start mode to “Always Running” tells IIS to start a worker process for your application right away, without waiting for the initial request.

The .NET CLR version is a little tricky. Normally, for an ASP.NET core application, we would set the .NET CLR version to “No Managed Code”, as suggested in the [hosting ASP.NET core application on IIS](#) documentation.

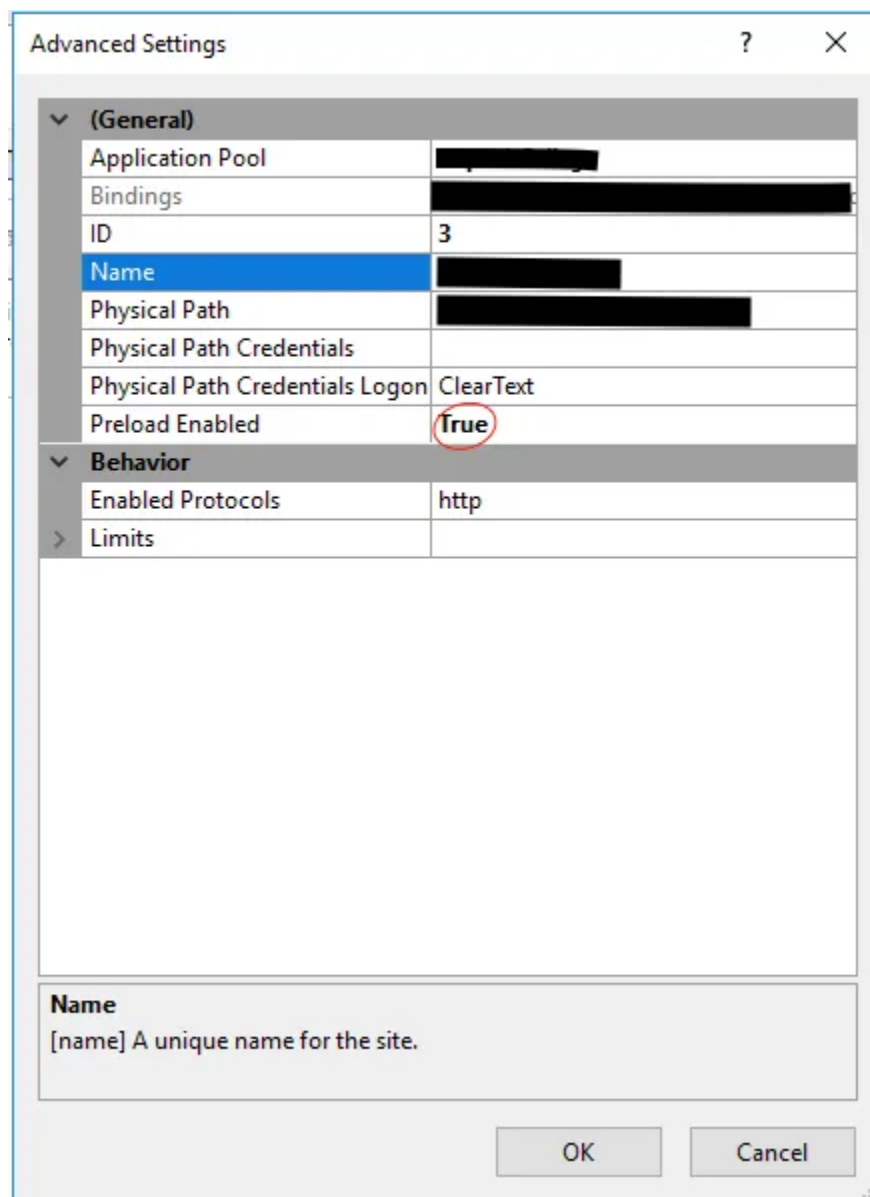

ASP.NET Core runs in a separate process and manages the runtime. ASP.NET Core doesn't rely on loading the desktop CLR.

However, I've found it is necessary to set the .NET CLR version for the other settings to work (application auto start and always run).

3. Configure the IIS site

↑

In IIS Manager, right click on the site for the application, select “Manage Website” -> “Advanced Settings” and set the “Preload Enabled” value to true.

The screenshot shows the 'Advanced Settings' dialog box for an IIS website. The 'General' tab is selected, and the 'Preload Enabled' checkbox is checked and circled in red. The 'Behavior' tab is also visible, showing 'Enabled Protocols' set to 'http'.

Advanced Settings	
(General)	
Application Pool	[Redacted]
Bindings	[Redacted]
ID	3
Name	[Redacted]
Physical Path	[Redacted]
Physical Path Credentials	
Physical Path Credentials Logon	ClearText
Preload Enabled	<input checked="" type="checkbox"/> True
Behavior	
Enabled Protocols	http
Limits	

Name
[name] A unique name for the site.

OK Cancel

That's it.

That's all I have to do to keep the ASP.NET core app running on IIS. Let me know if you have questions. Your feedback is also welcome.

The banner features the ASPHOSTPORTAL logo on the left, the ASP.NET Hosting Partner logo in the center, and a green call-to-action box on the right. The call-to-action box contains the text 'ANNOYED with SLOW website? HOST with us NOW >>' and a price tag 'Only \$5/mo' with an upward arrow.
